RPY-1.5Q

1.5 Amp QFN Package

Description

The RPY-1.5Q is an automotive grade constant current source buck regulator designed for driving high power LEDs. The integrated inductor means that a complete LED driver can be realized in a compact 3mm x 5mm x 1.6mm thermally-enhanced QFN package with a maximum current output of up to 1500mA set with an external sense resistor. The input voltage range is from 4 to 36VDC, allowing 5V, 12V, or 24V supply voltages to be used. The output is fully protected against continuous short-circuits, input under-voltage, output overcurrent, or over-temperature conditions. A fault indicator flags thermal shutdown or LED open/short circuit conditions. Applications include dimmable LED lighting, visible or IR LED illumination for drones and robotic camera systems, or precision high current CC sources for test and measurement use.

The RPY-1.5Q has fault indication (FAULT) which is the open drain of a MOSFET and should be connected to VCC or another voltage source through a resistor (e.g. 100kΩ). FAULT is pulled high during normal operation. During the error conditions of output short circuit, open circuit, or thermal shutdown, FAULT is pulled down to indicate a fault status.

Thermal Derating ($I_{OUT}= 1.5A$)

OUTPUT CURRENT SETTING

The external resistor R_3 divider sets the output current (see "Typical Application") and should be approximately 400mΩ. R_3 can then be calculated with below equation. The resistor (R_2) sets the feedback loop bandwidth. The lower the R_2 is, the higher the bandwidth. A high BW may cause insufficient phase margin, resulting in loop instability. R_3 Ensure that Sense resistor is capable of handling defined current. Thermal drift and resistor tolerance will have an impact on current stability.

Calculation:

$$I_{LED} = \frac{0.2VDC}{R_3}$$

Example:

$$I_{LED} = \frac{0.2}{0.4} = 0.5$$

V_{FB} [VDC]	I_{LED} [A]	R_2 [kΩ]	R_3 [Ω]
0.2	0.35	220	0.57
	0.5	200	0.4
	0.7	175	0.286
	1.05	150	0.19
	1.5	100	0.133

PCB LAYOUT SUGGESTION

Efficient PCB layout, especially of the input capacitor placement, is critical for stable operation. For best results follow the guidelines below.

1. Connect a large ground plane to PGND pins 14 and 15 directly. If the bottom layer is a ground plane, add vias near GND.
2. Ensure that the high-current paths at GND and VIN have short, direct, and wide traces.
3. Place the ceramic input capacitor close to VIN and GND.
4. Keep the connection of the input capacitor and VIN as short and wide as possible.
5. Place the external feedback resistors close to the chip.
6. Use multiple vias to connect power planes to internal layers.
